INTRODUCTION
Accounting for 7% of all fall-related injuries and over 30% of fall-related hospitalizations, hip fractures are a serious health concern for older adults. Costing an estimated 1.1 billion annually, ~25% of cases result in death within the first year of injury.

Previous experimental studies have shown the biomechanical effectiveness of interventions. Logistical and cost barriers have prevented the clinical effectiveness of certain interventions from being quantified.

The objective of this study was to use a mechanistic, probabilistic model of impact dynamics to predict the clinical effectiveness of safety flooring and hip protectors at reducing hip fracture risk.

METHODS

Probabilistic Model
Generating a Virtual Sample
A sample of 100,000 virtual individuals (VI) were generated to be representative of the older adult population in terms of physical characteristics (Height, Mass, Age, Sex).

This was done by defining the Canadian population probability distributions for each physical characteristic (example: Figure 1).

VIs were defined by drawing values pseudo-randomly along each defined distribution.

Mechanistic Model
Factor of Risk (FOR) principles were used to assess hip fracture risk, where:

\[ \text{FOR} = \frac{\text{Impact Force}}{\text{Bone Strength}} \]

When FOR > 1, Fracture Expected

Impact force and bone strength were calculated by using the physical characteristics of the VI in conjunction with previously defined equations.

Experimental Data
Developing Regression Equations
Data from studies investigating the effects of a hip protector (HipSaver, Figure 2A) and a safety floor (SmartCells, Figure 2B) on impact force during simulated lateral impacts (using human volunteers and a mechanical test system, respectively) was used to develop impact force attenuation regression equations based on the characteristics of the volunteers and the mechanical test system.

RESULTS

Simulations predict substantial reduction in hip fracture risk (Figure 4, Tables 1&2)

Table 1: Mean (SD) Factor of Risk for the Baseline, Hip Protector, and Safety Floor Conditions

<table>
<thead>
<tr>

</tbody>
</table>

DISCUSSION

• Proof of concept for performing “virtual” clinical trial to predict clinical effectiveness of experimentally tested interventions
• The model predicted a >20% reduction in the expected number of hip fracture cases with the use of these interventions; decreased risk of fracture
• Predicted clinical effectiveness of these interventions need to be validated against clinical trial data
• 4 year safety flooring clinical trial soon to be completed
